Newsletter

Volume 32. Number 1

March 2005

11:00 A.M. Discussion, Identification, Questions

12:00 Noon Insect Research Collection with Steve Krauth Bring a bag lunch. Snacks will be available.

> 1:00 P.M. **Election of Officers**

#### SPEAKER TOPICS

THE INVASIONS NEVER STOP! What's new in the arthropod world? Presenter: Phil Pellitteri

### **NEW WISCONSIN MOTH RECORDS**

Over 15 newly-recorded (and a few overlooked) moth species have been documented since the Checklist of Wisconsin Moths came out in 2000. Speaker will speculate on their status, as well as the spread of several introduced European Noctuids.

Presenter: Les Ferae

#### NAME THAT CATERPILLAR CONTEST

How many caterpillars will you be able to identify? A prize will awarded to the winner. Presenter: Janice Stiefel

Dear WES Members.

I know that some of you were less than satisfied with our November meeting and I am sorry. Our Spring meeting has been planned to make up for that. Phil, Les. Janice, and I all plan to attend and we need you as well. Bring your photos, specimens, questions, and a bag lunch and be prepared to visit. See you there!

Megan Kyslop, President

The Wisconsin Entomological Society Newsletter is published three times a year, at irregular intervals. It is provided to encourage and facilitate the exchange of information by the membership, and to keep the members informed of the activities of the organization. Members are strongly encouraged to contribute items for inclusion in the newsletter. Please send all news items, notes, new or interesting insect records, season summaries, and research requests to the editor:

Janice Stiefel, 2125 Grove Road, Bailey's Harbor, WI 54202, (920) 839-9796, e-mail: |stiefel@itol.com NOTE: Please report any address changes to Les Ferge, 7119 Hubbard Ave., Middleton, WI 53562. e-mail: ferge@chorus.net

### Readers' Answers to October 2004 MYSTERY INSECT

To refresh your memory, see photo at the bottom right

#### RON HUBER Bloomington, MN

"The October Mystery Insect appears to be the Ailanthus Webworm moth, Atteva punctella (Cramer) (formerly Atteva aurea Fitch in Holland's moth book). family Yponomeutidae. It is interesting that this native moth lays eggs primarily on an introduced tree species! The five native tree species of the Quassia family Simaroubaceae are all deep south and southwest. Perhaps if the Ailanthus (Tree of Heaven) hadn't been introduced here, we wouldn't have the moth in Minnesota. Of interest, my wife caught one A. punctella in western Kansas out on the prairie in the "middle of nowhere"" We looked around, and sure enough, there was a huge Allanthus towering over us. Must have been an old homestead once upon a time (no sign of it now) where they planted the tree. Way out there, but the little moth found it! (Or maybe came in with the tree 70 years ago)."

#### GENE DRECKTRAH Oshkosh, WI

"It's the Ailanthus Webworm Atteva punctella (Cramer) adult. Order: Lepidoptera. Family: Yponomeutidae

"I have four specimens in the university collection and three specimens in my personal collection (if that means anything)."

#### RICHARD BREEN Wisconsin Rapids, WI

"The October Mystery Insect looks like an Ailanthus Webworm Moth to me. That would be:

Family: Yponomeutidae Genus: Atteva

Species: punctella

Hobomok Skipper male (Poanes hobomok)

ingled with the butterfly population in Wisconsin, are the seemingly insignificant skippers. Many people think they are moths because of their chunkier bodies but they are butterflies that belong to the Hesperiidae (hes-pi-RY-i-dee) family.

Between the years of 1860 and 1870, three American lepidopterists by the name of Moses Harris. Samuel Scudder and W.H. Edwards, found themselves with the honor of naming the Skippers. Because the Indian tribes, along with their chiefs and leaders were being slaughtered at such an alarming rate and because they felt their

names would be lost forever, these three men decided to name some of the Skippers after Native Americans.

Of the three dozen or so Skippers found in Wisconsin, four with the most interesting past are:

Indian
Skipper
(Hesperta
sassacus). The
species name,
sassacus, was
named for the
last important
chief of the
Pequot tribe
which dominated land from

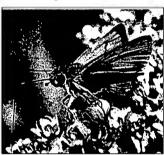

## What's In A Name?

The Naming of the Skippers

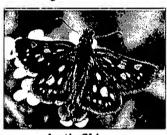

Text and Photos by Janice Stiefel

Indian Skipper male (Hesperia sassacus)

Delaware Skipper female (Atrytone delaware)

Arctic Skipper (Carterocephalus palaemon mandan)

Narragansett Bay to most of Long Island. Sassacus had great hatred for the colonists...probably because they killed his father. In 1836 the colonists waged war against his people, defeating them. Sassacus escaped into Mohawk territory with a small band of his men. The Mohawks had no pity or use for them, so they killed Sassacus, sending his scalp and those of six of his followers to the governor of Massachusetts.

Delaware Skipper (Atrytone delaware) is named for the Delaware tribe which inhabited New York, New Jersey, and Pennsylvania.

The Hobomok Skipper (Poanes hobomok) was named for Wampanoag Chief Hobomok, who lived in southeastern New England at the time of the Pilgrim's landing.

Long Dash

Skipper (*Polites mystic*) [photo not shown] was named for Mystic, Connecticut where the Pequot tribe was defeated in 1636.

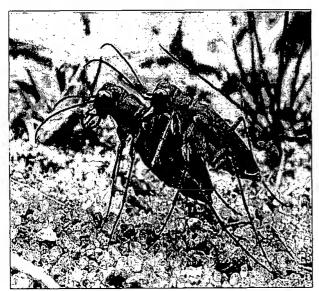

Arctic Skipper (Carterocephalus palaemon mandan) was named after a group of Sioux Indians who spoke the Mandan language and inhabited North Dakota in the area between the Heart and Little Missouri Rivers.

Besides adding to the diversity of Wisconsin insects, the heritage of the Skippers offers a history lesson, We can thank Moses Harris, Samuel Scudder and W.H. Edward for having the foresight to preserve Indian legacy.

ne of the joyous thrills of nature-watching is the unexpected, once-in-a-lifetime encounter. I know the moment is really special when it makes me stop in my tracks and stand there wide-eyed, and all I can say is, WOW! One such moment occurred on May 10, 1998.

Lund's Swamp is my affectionate name for a wonderful wetland mix of wet meadow, shallow marshy lake, cattail marsh, swamp woods, forested upland on sandy soil and forested ponds. On the map, this place is known as McDonald's Flowage, part of the Navarino State Wildlife Area in Shawano County. This wildlife refuge provides habitat for wood ducks, bald eagles, woodcocks, painted muskrats. turtles, wood frogs, mustard white butterflies, blackberries, winterberry, wood ticks, and dragonflies.

Picture the moment: about three o'clock on a sunny, warm (78°F) May afternoon. My husband, Jerry, and I slowly motor along the swamp road listening for spring sounds and watching for critters. A car approaches us and instantly a big black "cloud" appears over the road ahead of us. As soon as the car passes, the cloud disappears. Another car approaches us and the same thing happens. The black cloud reminds me of Alfred Hitchcock's. The Birds. The cloud looks like a giant flock of starlings flying in close formation: swirling, dipping, turning, rising as one except the individuals do not look like birds. This cloud also instantly disappears.

Now we approach the spot. As we drive slowly, the cloud instantly reappears and we are engulfed in the biggest swarm of darting, turning, zipping, flipping dragonflies I have ever witnessed. I yell "Dragonflies" and Jerry quickly stops the car. By the time I jump out of the car, the dragonflies are gone. Where are they?

I look around and notice a few transparent wings glistening in the sunlight. I step off the road to investigate and discover about 30 dragonflies clinging to the bare branches of a shrub. A few individuals rest with wings open, but most perch with wings closed up

THE DRAGONFLY DANCE

Spiny Baskettail Dragonfly (Epitheca spinigera) May 10, 1998 Navarino State Wildlife Area Shawano County, WI

over their bodies, looking like giant Mayflies. They are all lined up, resting at oblique angles, one right after another. Looking around and up, I discover other branches, both leaved and unleaved, bedecked with dragonflies. I expand my field of view and see more dragonflies. Motionless dragonflies are everywhere. I am surrounded by hundreds and hundreds of perching dragonflies, resting in the warmth of spring.

Just then another car passes, going about 45 MPH. The dragonflies erupt into flight, I hear the chorus of stiff membraneous wings fluttering at they effortlessly lift the insects. The startled dragonflies dart up, out and over the road. The black cloud swirls over my head. Amazingly, hundreds of dragonflies flying in very tight formation and there are no mid-air collisions. As soon as the car

passes, the dragonflies drop from the cloud to resettle on the vegetation. Most quickly land, equidistant from their neighbors, with no jockeying for position. Some lite on others, but quickly flit off to find an open spot. In just a few moments, all is quiet, hundreds of dragonflies resting, once again, motionless in the sunlight.

I just stoof there and said, "WOW!" Knowing that no one picture could capture the total scene, the sounds, or the feeling of being surround by all these incredible dragonflies as they take flight and then resettle. I hoped for another car to pass.

These dragonflies are Spiny Baskettails (Epitheca spinigera), inhabitants of marshy lakes. Lund's Swamp is an ideal home. These individuals had recently emerged as their wings had not yet hardened into their permanent horizontal positions. Swarming is something this species may do upon emergence. Why and how long they swarm, I do not know.

I hated to leave for I knew the swarm would soon dissipate with individuals staking out their ideal spot in Lund's Swamp. That warm May day, I had been in the right place at the right time. More importantly, I was aware that something unusual was happening and I took the time to investigate. I still get excited when I think of how lucky I was to experience this phenomenon. WOW!

WES member Anita Carpenter is a pharmacist by profession and a naturalist by passion. Her nature articles regularly appear inside the front cover of Wisconsin Natural Resources Magazine.

Spiny Baskettails have dull metallic green eyes. They are medium-sized and dark, with orange spots on the sides of their abdomen. They sometimes feed in swarms and inhabit marshes, borders of lakes and slow streams.

From Dragonfiles of Wisconsin Edition 4.0 2003 by Karl & Dorothy Legler with Dave Westover

## 2004 WISCONSIN LEPIDOPTERA SEASON SUMMARY

Coordinator: Leslie A. Ferge

Contributors Cited: James A. Ebner (JAE), George J. Balogh (GJB), Leslie A. Ferge (LAF), Kyle E. Johnson (KEJ), Waldemar E. Kmentt (WEK), Janice J. Stiefel (JJS), Ann & Scott Swengel (SAS).

Temperatures were below average for most of the season, with frequent and often heavy rain prevalent. Spring conditions were cool and wet, with May being one of the wettest in recent memory. Dismal conditions hampered field work and delayed emergences of many spring species. Summer was erratic, with August temperatures being far below average but September above average. Numbers of most butterfly species continue to be significantly depressed, and moth numbers seemed less than usual as well. It was not a particularly good season for migratory butterflies. *Pyrgus communis* and *Euptoieta claudia* were recorded northward early in the season, but few other species were seen in August and September. Interestingly, JAE found very late season arrivals of several species in SE Wisconsin in October. Monarchs arrived later than average, but numbers remained very low throughout the season.

The records are arranged systematically by checklist number, following the Checklist of the Lepidoptera of America North of Mexico (Hodges et al., 1983). New county records are indicated by county names appearing in CAPITAL letters. Abbreviations used in the data include: CF = County Forest, SF = State Forest, SNA = State Natural Area.

#### **MYSTERY INSECT**

Can you identify it?

This caterpillar stands out from the rest because it has an extra set of prolegs at A5 and <a href="fringe-like">fringe-like</a>, pale hairs running along the length of the lower abdomen. The ground color varies from gray to brick red, or less commonly, smoky green. Each of the tan spiracles is ringed with black. Generally the mature larva is said to be about 1-1/2 in. long, but this individual was 2 in. Send common and scientific name to the editor. Individuals with correct answers will be announced in the next issue of the WES Newsletter.

Please make check payable to WES and send to Les Ferge, 7119 Hubbard Ave., Middleton, WI 53562-3231. he caddisfly (Agapetus hessi), a state "Special Concern" species, is the only member of its genus documented from Wisconsin. Dr. Hilsenhoff<sup>(1)</sup> indicates that two other species, A. rossi and A. tomus, also likely occur in the state. Records in the files of the Wisconsin Department of Natural Resources (DNR) suggest that a fourth species, A. illini, might also be added to the state's fauna.

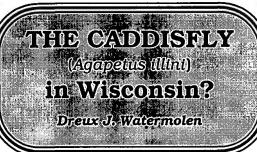

While preparing a water quality management plan for the Upper Green Bay Basin, I examined a series of data sheets with the results of a northern Wisconsin field study conducted in May 1980. The

DNR investigator collected aquatic insects from the Pike River and its major tributaries Marinette County. He found larval caddisflies of the a m i l y Glossosomatidae at six of eleven sampled sites. Members of the widely distributed genus Glossosoma occurred at four sites.

In addition, the investigator identified specimens collected at two sites (North Branch Pike River at Lily Lake Road and Little South Branch Pike River at Nutt Road) on 15 May as A. Illini, a possible new state record.

One can easily recognize larvae of the family Glossosomatidae by their small anal claws and

saddle-shaped or turtle-like cases (see accompanying figures. Identification of Agapetus species, however, poses a challenge; only adult males can be identified to species level with certainty<sup>(2)</sup>. The DNR data sheets, unfortunately, indicate neither the

sex nor the identifying characteristics used by the investigator, and voucher specimens are no longer available to confirm his identification.

The genus Agapetus occurs rarely in northern Wisconsin<sup>(1)</sup>, and A. illini has previously been reported only from Arkansas, Kansas,

Missouri, Oklahoma, Illinois, Indiana (where the state considers it a threatened species), Kentucky, and the Great Smoky Mountains National Park(2.8.9). Nevertheless, Hilsenhoff and his colleagues<sup>(3)</sup> reported collecting unidentified Agapetus from the nearby Pine-Popple River system. The possibility that these were A. illini should not be dismissed without further investigation. Agapetus has a very low tolerance for organic pollution<sup>(4, 5)</sup> and occupies only cool or cold streams<sup>(6, 7)</sup>. The field data sheets indicate the investigator noted excellent water quality at both collection sites and biotic index values(4) confirm that perception.

Even though the investigator was a competent field biologist, the possibility of misidentification cannot be overlooked, especially since the identifications were based on larvae. Therefore, we should not consider A. illini a component of Wisconsin's fauna at this time. Investigators working in northern Wisconsin streams with excellent water quality, nonetheless, should be on the look out for additional Agapetus specimens. Such collections could help further elineate the Wisconsin distribution

delineate the Wisconsin distribution of this genus and might shed light on this interesting, but questionable, occurrence.

widespread member of the

family Glossosomatidae

(from Ross, 1944)

Dreux Watermolen is a member of WES. He is an ecologist interested in the zoogeography, life history, and taxonomy of Wisconsin's rich biological diversity. The European Corn Borer (Ostrinia nubilalis) came to America in 1917, in an unusual way, not hitch-hiking in corn at all. Instead this small moth

came in brooms made in Hungary and Italy. How is that possible? Brooms are made from broomcorn sorghum, a relative of corn and one of the borers' many foods. The pupae of the moths were hidden in the straws of the brooms. Apparently, the boat ride to the US was pleasant.

The moths emerge from their over-wintering pupae in May and June and fly to a nearby field to lay about twenty eggs in a quarter-inch white mass per leaf. In about a week, the eggs turn dark and the hatchlings move out as first instar larvae or borers. About every two weeks a larvae sheds its skin and passes through second, third, and fourth instar stages. The borer is fully grown by the fifth instar stage and pupates in the stalks and leaves. The second brood moths emerge from the pupae in July and August and they flit and flirt in the weeds along the cornfields.

These summer moths mate and then the females lay eggs that become the second generation. Even a third generation is possible if the weather is favorable for a longer growing season. These larvae can

over-winter as borers that do not pupate until spring. So you see, a few adult moths can cause a large population of borers since each female can lay over 500 eggs in her short lifetime.

Borers get around, with all those legs, and can bore

into the tassels, the ears, the ear shanks, and the stalks. The plant is weakened and produces fewer ears of corn with smaller kernels. However, cooler-than-normal temperatures can chill any ovipositor in the first brood. In the second generation, if the weather is hotterand-drier than usual, a Beauveria fungus often dines on and in the

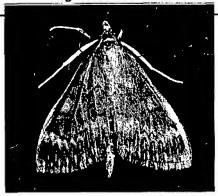

European Corn Borer Larva

larvae, covering it with a cottony white mass. It's not easy being a moth-er of a borer. The female lays her eggs, but now scouts (people) walk the cornrows and look for the egg masses. With a formula based on the number of eggs per plant, the scouts estimate the amount of insecticide the farmer could apply to the corn field. "Could apply" is a key phrase here, because pesticides are expensive and cost-benefit analysis is studied before making that decision to spray.

If the eggs have already hatched, scouts look for tiny but shiny "windows" in the leaves created when the first instars feed on

Just the epidermis and mesophyll layer, but can't eat all the way through the leaf yet. After that breakfast, they have enough strength to chew into a leaf, tunnel down a vein, then eat their way down the stem. If they make it. A good rainstorm can knock them off, as will stiff

winds. Hot weather can dry them up if they don't squirm on down the leaf whorl soon enough. Yes, life is tough in the borers struggle of life. But still, population-wise, borers are successful because they can eat over 230 species, including cotton, some vegetables, and weeds alongside the fields. But corn of all kinds are their favorites, popcorn, seedcorn, sweet-

corn, as well as sorghum raised for bird food and brooms. So the scouts are checking other crops as well, looking for other clues of the borers presence.

One is "Shotholes," which are small holes eaten entirely through the middle of a leaf, but not toward the tips. The middle of the leaf is a bad place for borer tunnels because the leaf will break easily in the wind or rain. A scout may slit the corn midrib and find the borer, easily identified by their black head and light-colored body. The other sign that trained scouts and entomologists can spot before any one else is frass...the tiny particles of excretement. Ahah!

Good news is the borers do not feed on seedling plants. The bad news for farmers is: there are a lot of other insects that do. So, is it borers: 10 and humans: 0 in the game card of life? Not in our generation. The humans have struck back in an unprecedented manner. Instead of applying insecticide to the plants, the plants are genetically modified with a gene from Bt, the bacterium that kills the borer stage. So borer eats, and borer dies. No next generation. The process of genetransfer in the making of Bt corn is called biotechnology. The transgenic crop or GMO is a genetically modifled organism that is patented and carefully controlled so farmers will not save the seed for the next season of planting. The concern over GMO's may be outpaced by farmers in the US, Canada, China and Argentina who are increasingly planting the new corn hoping to raise yields yet reduce pesticide costs. While cultural controls, such as burning the stalks or plowing them under, does reduce local over-wintering corn borer populations, the moths still can fly in from other fields. Our native lady beetle, Coleomegilla maculata, is a natural predator on the egg masses. In some areas, wasps such as Eriborus terebrans and Macrocentrus grani parasitize the 2nd to 4th instar larvae. 🤻
